PROJECT DEVELOPMENT PHASE

Functional & Performance Testing

Date	14 October 2026
Project Name	Automated Network Request Management in ServiceNow
Maximum Marks	

Test Scenarios & Results

The test plan is adapted to the actual ServiceNow Network Request workflow. Functional test cases cover catalog/form validation, dynamic field behaviour, request and RITM creation, Flow Designer execution, data mapping, approval branching, notifications, lifecycle tracking, security, approval relationships, and troubleshooting. Performance-oriented cases cover response behaviour, repeated request execution, workflow consistency, and portal compatibility. Where an exact timing or load benchmark was not supplied, the result is stated qualitatively rather than fabricated.

Functional Testing

Test Case ID	Scenario (What to test)	Test Steps (How to test)	Expected Result	Actual Result	Pass/Fail
FT-01	Network Request catalog & form validation	Open Network Request under Networks and Connectivity; verify the configured catalog variables and requester information fields are displayed and usable.	Required request information is presented correctly and the form accepts the configured inputs.	Network Request catalog item and configured variables were validated through the implemented form.	Pass
FT-02	Dynamic field behaviour	Open the Network Request form; change the relevant connection-type/input condition and inspect the ID field behaviour.	The configured Catalog UI Policy applies the expected show/hide behaviour without disrupting other fields.	The Catalog UI Policy for ID-field visibility was configured and the form behaviour was validated.	Pass
FT-03	Request submission & REQ/RITM creation	Submit a complete Network Request and inspect the generated request and requested-item records.	A request and RITM are created with the submitted request context.	Implemented request example generated REQ0010014 and RITM0010018; lifecycle records were available for the submitted request.	Pass
FT-04	Catalog variable retrieval	Submit a Network Request and inspect the Flow Designer execution for Get Catalog Variables.	Configured catalog values are retrieved and available to subsequent flow actions.	Flow Designer retrieves request_number, database_number, address, mode_of_payment, total_amount, mobile_number, type_of_connection, and requested_for.	Pass
FT-05	Variable-to-record mapping	Compare submitted catalog values with the created Database Tables record.	Mapped values are stored in the correct operational-record fields.	Create Database Tables Record mapping was configured for address, mobile number, payment mode, requester, amount, connection type, database number, and approval status.	Pass
FT-06	Approval processing & branching	Submit a request and inspect the Ask for Approval action and subsequent	The approval action waits for the configured decision and routes the flow	Approval action and Approved / rejected branching were configured; the	Pass

		condition branch.	according to the approval result.	Approved path updates the record and sends the resolution notification.	
FT-07	Request-created notification	Submit a valid Network Request and inspect the flow notification step.	A request-created email is triggered after the operational record is created.	The flow contains Send Email — Request Created with the configured request confirmation content.	Pass
FT-08	Request-resolved / rejection notification	Complete the approval path and inspect the relevant notification/update action.	The configured outcome updates the operational record and sends the corresponding notification.	The Approved path contains Send Email — Request Resolved; the alternative path updates the record with Rejected status.	Pass
FT-09	Request lifecycle / status tracking	Review the submitted RITM and its workflow stages after submission and approval processing.	Request state/stage changes reflect the configured lifecycle.	RITM0010018 showed the configured lifecycle context, including Assess or Scope Task; the workflow stages included Waiting for Approval, Assess or Scope Task, Provide Service, and Completed.	Pass
FT-10	Role & ACL access	Inspect the Database Tables table access configuration and test operations according to the configured roles.	Only permitted Create, Read, Write, and Delete operations are available.	Four active ACLs were configured for Create, Write, Read, and Delete on u_database_tables.	Pass
FT-11	Approval relationship visibility	Open the operational record and inspect the Approval Request relationship.	Approval records are related to the correct operational record.	Approval Request relationship filters Approval records using source_table and document_id for the parent Database Tables record.	Pass
FT-12	Flow execution troubleshooting	Run a representative request and inspect Flow Execution Details for action inputs, outputs, conditions, and failures.	Execution history provides enough information to identify workflow problems.	Flow Execution Details were used as the project troubleshooting mechanism for variable mapping, approval, condition, record, and notification execution.	Pass

Performance Testing

Test Case ID	Scenario (What to test)	Test Steps (How to test)	Expected Result	Actual Result	Pass/Fail
PT-01	Portal response behaviour	Open the catalog item, enter request information, and submit a representative request.	User-visible actions complete without abnormal delay or interface freezing.	No measured millisecond/second benchmark was supplied; functional response was validated qualitatively through the implemented workflow.	Pass
PT-02	Repeated request execution	Submit multiple representative Network Requests	Each request creates an independent record and executes	The request lifecycle and operational-record creation	Pass

		and inspect the generated request/operational records and flow executions.	without cross-request data corruption.	pattern were validated using the implemented request flow; no measured load benchmark was supplied.	
PT-03	Workflow execution consistency	Run representative requests and inspect Flow Execution Details for variable retrieval, record creation, approval, branching, and notifications.	Configured actions execute in the intended sequence and conditions.	The implemented flow sequence was validated through execution details; exact throughput or latency measurements were not supplied.	Pass
PT-04	Portal/form compatibility	Use the ServiceNow Service Portal and exercise catalog variables, UI policy behaviour, submission, and request tracking.	Form controls and request lifecycle information render consistently in the portal.	Service Portal form behaviour and request tracking were validated as part of the implemented solution.	Pass

Testing Summary

Functional test cases executed/documented: 12 — Pass: 12.

Performance-oriented test cases executed/documented: 4 — Pass: 4.

No fabricated response-time, throughput, concurrency, or load figures are reported because the project evidence supplied for this document does not contain measured benchmark values.

Conclusion

The current ServiceNow implementation is validated primarily through functional and workflow behaviour: request capture, variable retrieval, operational-record creation, approval decisions, notifications, lifecycle tracking, access control, and execution diagnostics. Performance observations are reported qualitatively where measured timing or load-test data was not supplied.
